Covalent Bonding Map

Edexcel A Level Chemistry · Topic 2 Bonding and Structure · Covalent Bonding

1 The covalent bond 2A.7

- Non-metal atoms **share** a pair of electrons
- Both **nuclei attract** the shared pair between them
- A strong electrostatic attraction
- Attraction to the pair outweighs nuclear repulsion
- Giant covalent solids: very high melting temperatures

2 Dot-and-cross diagrams 2A.8 i

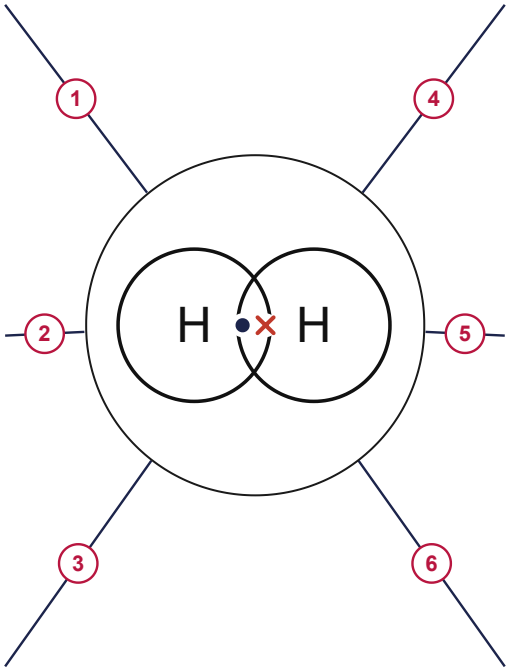

- Outer shells overlap; shared pairs in the overlap
- Dots for one atom, crosses for the other
- **Lone pairs**: unshared outer pairs
- Usually 8 round each atom (2 for H)
- Double bond: 2 pairs (O=C=O); triple: 3 (N≡N)

3 Bond length and strength 2A.9

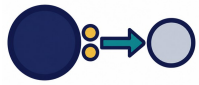

- **Bond length**: distance between the two nuclei
- Attraction to the pair balances nuclear repulsion
- More shared pairs: shorter, stronger
- C≡C 120 < C=C 134 < C–C 154 pm
- C=C: σ + π, stronger but not twice C–C

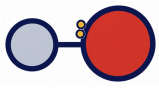

4 Dative covalent bonds 2A.8 ii

- Both shared electrons from **one atom**
- Donor: a **lone pair**; acceptor: an **empty orbital**
- Drawn as an arrow: $H_3N \rightarrow H^+$
- NH_4^+ and H_3O^+: brackets and + round the ion
- Al_2Cl_6: two Cl→Al dative bonds

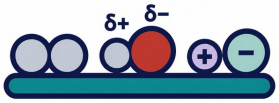

5 Electronegativity 2A.13

- Attraction of an atom for a **bonding pair**
- Pauling scale: F 4.0 the highest
- **Increases across** a period: more protons
- **Decreases down** a group: larger, more shielded
- O 3.5, N 3.0, Cl 3.0, C 2.5, H 2.1

6 Polarity and the continuum 2A.14

- Different electronegativities: a **polar** bond
- δ− on the more electronegative atom
- Difference 0: non-polar; small: polar covalent
- Large difference: **ionic**, electron transferred
- Ionic and covalent: ends of one **continuum**

Electronegativity difference and bond type

Pauling values; the boundaries are gradual, not sharp

Bond	Electronegativities	Difference	Partial charges	Bond type
Cl–Cl	3.0, 3.0	0	none	non-polar covalent
C–H	2.5, 2.1	0.4	almost none	almost non-polar
H–Cl	2.1, 3.0	0.9	Hδ+ Clδ−	polar covalent
O–H	3.5, 2.1	1.4	Oδ− Hδ+	polar covalent
Al–Cl	1.5, 3.0	1.5	Alδ+ Clδ−	polar, ionic character
Na–Cl	0.9, 3.0	2.1	Na^+ Cl^-	ionic

Worked examples

Drawing a molecule

- Count outer electrons of each atom
- Share until each has 8 (H: 2)
- Add the lone pairs last

Spotting a dative bond

- Is there a lone pair (N, O, Cl)?
- Is there an empty orbital (H^+, B, Al)?
- Arrow from the lone pair to it

Comparing bonds

- More pairs: shorter, stronger
- Bigger difference: more polar
- Very big difference: ionic

Polar bonds do not always make polar molecules: the shape decides (Shapes of Molecules).
